## ABSTRACT

Two recent computer programs, WRCOMP and ENGINE, by A. Mathur, were used to examine the performance to be gained by incorporating a wave rotor component in a turbofan engine with mixed exhausts. The programs were transferred to a VAX-2000 computer, extended, and test cases reported by A. Mathur were successfully reproduced. A comparison was made between ENGINE, in which real gas effects are accounted for, and ONX (by J. Mattingly) in which constant specific heats are used. The inclusion of real gas effects proved to have a significant impact on the predicted performance. An extension of Mathur's results was made by varying the overall pressure ratio in the wave-turbofan engine. Further cycle studies and experiments to measure wave rotor component performance are recommended.

SFC	Specific fuel consumption
SPR	Static Pressure Ratio
$\tau = TTR$	Total Temperature Ratio
T	Temperature
TIT	Turbine Inlet Temperature

ACKNOWLEDGMENTS

Thanks to my best friend and wife, Kim Roberts, for her support and encouragement, and to Ray Shreeve, for making this a challenging and rewarding experience.

The work is dedicated to our son, Adam James Roberts.

## I. INTRODUCTION

Interest by DARPA (Defense Advance Research Projects Agency) and NAVAIRSYSCOM (Naval Air Systems Command) in obtaining increased range for unmanned air vehicles (UAV's) prompted the present study of wave rotor applications in engines. The wave rotor offers potential to achieve lower specific fuel consumption (SFC) and higher specific thrust by allowing increased cycle temperatures without increasing turbine inlet temperature. The goal of this study was to examine the potential benefits of incorporating a wave rotor in a turbofan engine with mixed exhausts. The results showed that significant benefits could be obtained in both SFC and specific thrust depending upon the selection of other cycle parameters.

Chapter II describes the wave rotor concept, presents a general background on trends in gas turbine technology, gives a description of a wave rotor engine component and introduces the two computer programs (ENGINE and ONX) which were used in the study. Chapter III gives a detailed description of the ENGINE code and presents a comparison of results obtained with ENGINE and ONX. Chapter IV gives a description of the WRCOMP program, which analyses the unsteady wave rotor flow, and its interface with the ENGINE program. Chapter V gives results obtained using the codes for the performance of a turbofan

with mixed exhausts, with and without a wave rotor component. Conclusions and recommendations for further work are given in Chapter VI. Details are given in the appendices. Appendices A and B contain procedural guides, sample results and program listings for ENGINE and WRCOMP, respectively, while Appendix C describes file transfer and graphics procedures which were used in the course of the study.

## II. BACKGROUND

### A. POTENTIAL FOR WAVE ROTOR APPLICATIONS IN ENGINES

A wave rotor is a partial admission device which causes one gas to compress another by wave propagation [Ref. 1:p. 1]. A series of straight compression tubes are aligned on a rotor encased in a drum. The rotor rotates on a fixed axis. Flow in and out of the wave rotor is steady while flow inside the wave rotor tubes is unsteady. Figure 1 shows an example of a wave rotor component. The single wave rotor component serves the same function as the combination of a compressor and a turbine mounted on the same shaft.

Figure 1. Wave Rotor Component [Ref. 1:p. 294]

Figure 2 shows a turbofan engine configured with an axially mounted wave rotor component.

Figure 2. Wave Rotor Turbofan Engine [Ref. 1:p. 293]

Development of wave rotor devices for engines began in the early 1950's. By the early 1960's, gains were achieved in performance through improved seal design and improved timing of the waves arriving at inlet and outlet ports ("tuning") [Ref. 1:p 174]. Few developments were attempted after the 1960's, except by Brown-Boveri in Switzerland. The Brown-Boveri "Comprex" is presently being produced as a commercial supercharger and is available in trucks, heavy equipment and Mazda diesel automobiles. Reference 1 provides a comprehensive review of wave rotor technology.

Wave rotor components have promising applications in small engines in the 600 to 1000 lb. thrust range. Such engines have applications in cruise missiles, remotely piloted vehicles (RPV's), helicopters and small thrust turbofans. The more conventional approach, however, has been to pursue increased turbine inlet temperatures in conventional gas

turbine engines to achieve the desired improved performance. However, in the process, the requirement for turbine cooling also increased. The wave rotor offers the potential to increase performance without the attendant necessity for cooling.

Studies of engine performance indicate that a wave rotor component must be included in the initial cycle optimization rather than be added to an existing engine design. Wave rotor components require, optimally, different compressor and fan pressure ratios. The inclusion of a wave rotor reduces the number of stages required for compression to a constant cycle pressure ratio and allows higher maximum temperatures in the cycle for the same turbine inlet temperature. Performance predictions for gas turbine engines incorporating wave rotor components show decreased specific fuel consumption and increased specific thrust for any fixed value of turbine inlet temperatures.

Figure 3 shows the gains that are thought to be achievable in the performance of small engines [Ref. 1:p. 292]. In Figure 3, "near term improvements" include higher rpm (for a given engine size) and higher turbine temperatures. "New engines" will include composites, ceramics, or new materials. Some current "revolutionary engines" include the compound cycle, the eccentric, the recuperated and the wave rotor engine [Ref. 1:p. 292]. The conventional, eccentric and the recuperated engines are fundamentally limited by the maximum allowable

Figure 3. Trends in Engine Development [Ref. 1:p. 292]

turbine inlet temperature (TIT) [Ref. 2:p. 60]. The wave rotor engine is the only engine that promises significantly increased performance without requiring an increase in TIT [Ref. 1:p. 293].

#### B. ENGINE PERFORMANCE CODES

Two engine performance codes were available for the present study, ENGINE and ONX. There were some differences between the two programs. ENGINE calculated real gas effects based on fuel-air ratio and temperature, while ONX used constant specific heats at the compressor outlet and

downstream of the turbine inlet station. In both programs, the engine performance is obtained by equating power balances across the turbine and compressor sections, and describing an expression for the enthalpy rise across the burner section.

Program ENGINE was developed by A. Mathur [Refs. 3; 4], and uses notation developed by Vavra [Ref. 5], and Vanco [Ref. 6]. The program calculates the performance of a turbofan engine with mixed exhausts with and without the wave rotor component.

Program ONX was developed by J.D. Mattingly [Ref. 7], and it uses methods and notation developed by G. C. Oates [Ref. 8]. The program calculates the performance for a variety of engine configurations including a turbofan with mixed exhausts.

#### C. WAVE ROTOR INTERNAL FLOW DESCRIPTION

In 1984, A. Mathur developed a FORTRAN program (WRCOMP) to analyze the unsteady processes in wave rotors [Ref. 9]. A detailed description of the analysis and code are provided in Reference 9. WRCOMP uses a 1-D, random choice method (RCM) to solve the hyperbolic, nonlinear conservative system of equations by solving localized Riemann problems. Shocks have sharp resolution. Discontinuities are modelled as jumps. The code is first order accurate in time and it is unconditionally stable. Further explanations and details on the Random Choice

Method are given by Glimm [Ref. 10], Chorin [Ref. 11], and Sod [Ref. 12].

WRCOMP calculates the unsteady process inside the wave rotor, outputs the inlet and outlet port opening and closing times required for correct design, and computes the performance of the wave rotor given the total pressure ratio (TPR), the static pressure ratio (SPR), the exit Mach number (AMEXIT) and the (initial) reference density inside the wave rotor. The performance calculations depend on a favorable comparison for the mass flow rate into and out of the wave rotor component. The outputs from WRCOMP are used as inputs to engine performance calculations performed using the ENGINE code.

### III. ENGINE PERFORMANCE CODE

#### A. DESCRIPTION OF THE CODE

A complete listing, procedural guide and sample results for ENGINE are provided in Appendix A. The code incorporates modular subroutines to calculate each section of the engine cycle. A complete derivation of the code can be found in Reference 4.

The following changes were made to improve the utility of the code:

- (1) The original data statement format was modified for a user input interface;
- (2) A pop-up menu depicting the configurations was added (see Appendix C for details);
- (3) An altitude table was incorporated to automate ambient conditions using Reference 13;
- (4) A graphics plotting routine was added using GRAFkit software, Reference 14;
- (5) A loop was constructed to increment for:
  - a) bypass ratio,
  - b) fan pressure ratio,
  - c) compressor pressure ratio,
  - d) LPT exit Mach.

A complete listing of the input parameters and a sample output result appears in Appendix A.

ENGINE (and ONX) computes engine performance in terms of uninstalled specific thrust and specific fuel consumption.

The uninstalled specific thrust is defined as the thrust per unit mass flux through the engine and determines the engine size. The specific fuel consumption is the mass flow rate of fuel per unit thrust and determines the range. A power balance is written for each turbine and compressor spool. An enthalpy rise is written for the flow through the combustor. ENGINE uses loss coefficients and efficiencies to account for component performance. The program also uses real gas effects based on fuel air ratios and temperature. In contrast, ONX uses pressure ratios and polytropic efficiencies to account for component performance and assumes constant specific heats across the compressor ( $C_p_c$ ) and downstream of the combustor ( $C_p_t$ ). A necessary step, prior to the use of ENGINE, or comparison between ENGINE and ONX, was to reproduce the results reported by A. Mathur in Reference 4. These results were successfully duplicated using the inputs given in Reference 4 and Appendix A.

To achieve an accurate comparison between ENGINE and ONX, the polytropic efficiencies required in ONX were computed from the outputs of the ENGINE code using the component efficiencies, the actual and isentropic pressures and temperatures, and gamma. A sample calculation is provided in Appendix A.

#### B. COMPARISON WITH ONX CODE

Since engine cycle calculations are greatly affected by the inputs, especially the component efficiencies, an accurate

comparison between ENGINE and ONX could only be performed if the flight parameters, the design choices, the design limitations and the component efficiencies were the same. Flight parameters include the flight Mach number and the altitude. Design choices include the maximum temperature in the burner, the lower fuel heating value, the maximum turbine inlet temperature, the low pressure turbine exit Mach number, the compressor pressure ratio, the fan pressure ratio, the bypass ratio, etc. Fans, compressors, burners, turbines and nozzles are characterized by component efficiencies, which are the complements to the loss coefficients. The simplest test case for comparison of ENGINE and ONX was the non-afterburning turbojet. ENGINE calculated the turbojet case by setting the bypass ratio equal to zero.

### 1. TURBOJET

With all input and component performance parameters matched, the results of ENGINE were compared to those of ONX for the case of the turbojet. The results are shown in Table I. For the ONX (1) case, the  $Cp_c$  and  $Cp_t$  were selected to be in the range that Mattingly referred to as "typical" values [Ref. 7:pp. 116, 438]. The ONX (2) values for  $Cp_c$  and  $Cp_t$  were the result of numerous iterations using ONX to try to achieve agreement with ENGINE. The ONX (3) values for  $Cp_c$  and  $Cp_t$  were obtained by computing the average values for  $Cp_c$  and  $Cp_t$  from

TABLE I  
TURBOJET PERFORMANCE COMPARISON

$M_0 = 0.79$ ,  $h=35000$  ft.

ENGINE:  $F/m = 41.88$  lbf/(lbm/sec)  
 $SFC = 0.899$  (lbm fuel/hr)/lbf thrust

	ONX (1) Typical Specific heats	ONX (2) Values req'd for agreement	ONX (3) Average from ENGINE results
$Cp_c$	0.235	0.235	0.2434
$Cp_t$	0.295	0.251	0.2508
$F/m$	55.18	40.04	35.94
SFC	0.992	0.954	1.001
% Difference $F/m$	31.76	4.38	14.18
% Difference SFC	10.34	6.10	11.34

the ENGINE program output data. The differences were seen to be surprisingly large

A comparison table was constructed of the pressure and temperature into each component to trace where the calculations began to diverge. The divergence was found to occur in the enthalpy rise calculation across the combustor. For ONX, the enthalpy rise gives the fuel-air ratio ( $f$ ) as

$$f = \frac{Cp_t \times T_{t4} - Cp_c \times T_{t3}}{[Cp_f \times T_{tf} + h_v \times \eta_b] - Cp_t \times T_{t4}} \quad (1)$$

and the test case in Table I gave  $f = 0.0152$ . For ENGINE, the fuel-air ratio equation was:

$$f = \frac{A(T_{t4}) - A(T_{t3}) + f_i \times [B(T_{t4}) - B(T_{t3})]}{[Cp_f \times T_{tf} + h_v \times \eta_b] - B(T_{t4})} \quad (2)$$

where,

$$A(T) = C_1 \times T - \frac{C_2}{2} \times T^2 + \frac{C_3}{3} \times T^3 - \frac{C_4}{4} \times T^4 + \frac{C_5}{5} \times T^5 \quad (3)$$

and

$$B(T) = D_1 \times T + \frac{D_2}{2} \times T^2 - \frac{D_3}{3} \times T^3 + \frac{D_4}{4} \times T^4 - \frac{D_5}{5} \times T^5 \quad (4)$$

With  $f_i = 0.0$  (f prior to the burner), the test case designated ONX (1) in Table I gave  $f = 0.0103$ . Thus ONX calculated a 32.24% higher value for the fuel air ratio than did ENGINE. The question then was, can agreement be obtained between ONX and ENGINE using any reasonable values of the  $Cp$ 's in ONX. The result of an attempt to achieve such agreement is shown as ONX (2) in Table I. Using  $Cp_c = 0.235$  and  $Cp_t = 0.251$ , the disagreement in specific thrust was reduced to 4.4% and in SFC to 6.1%. It is noted here that the  $Cp$  value for air at the temperature at the exit of the combustor ( $1860^{\circ}\text{R}$ ) in the

present example is  $C_p = 0.271$ , considerably higher than the value required to approach agreement.

One further attempt was made to compare the code predictions for a turbojet. Values of  $C_p$  were calculated at the inlet and outlet stations of the compressors and turbines using the enthalpies calculated at the stations by ENGINE in the expression,  $h = C_p T$ . An average of the in and out values was then used as an input to ONX. The results are shown as ONX (3) in Table I. The strong sensitivity of the performance to the values used for the specific heats is evident in the comparison of the results of ONX (3) with ONX (2).

The selection of  $C_p$  values, therefore, had a significant affect on the performance calculations for specific thrust and specific fuel consumption. In order to examine the sensitivity to specific heats, ONX was run with varying  $C_{p_t}$  and varying  $C_{p_c}$ . Figures 4 and 5 show the affect that  $C_{p_t}$  and  $C_{p_c}$  had on the specific thrust and SFC given by the ONX code. The sensitivity to the selection of the input values for ONX is clearly evident in these figures.

A complete deviation of the real gas equations programmed in ENGINE can be found in Reference 3. Further details can be found in References 5 and 6. In short, the stoichiometric combustion equation for a general hydrocarbon fuel  $(CH_2)_n$  is expressed as a polynomial expansion. The constants in the expansion  $C_1$  to  $C_5$  and  $D_1$  to  $D_5$  in Equations

Figure 4. Effect of  $C_{p_t}$  on Specific Thrust and SFC

$$(\gamma_c = 1.4, \gamma_t = 1.350, CP_c = 0.2434)$$

(3) and (4) are derived from the constituents of the combustion gases. The final form of the enthalpy rise for the combustor is given as Equation (2). Thus  $C_p$  is effectively, and properly, a function of fuel-air ratio and temperature. Since the ENGINE code calculated the enthalpy using the fuel-air ratio and temperature rather than maintaining constant

Figure 5. Effect of  $Cp_e$  on Specific Thrust and SFC

( $\gamma_c = 1.400$ ,  $\gamma_t = 1.350$ ,  $Cp_t = 0.2508$ )

values for specific heats, the ENGINE code results were now considered to be more reliable than the ONX results.

## 2. TURBOFAN

After successfully reproducing A. Mathur's results [Ref. 4:p.7] for a turbofan with mixed exhausts, a comparison between ENGINE and ONX was carried out for the same engine.

The average values of  $C_p$ 's given by the ENGINE results were input into ONX. The results are presented in Table II. The percent differences in the specific thrust and SFC, predicted by ONX in comparison to ENGINE were 11% and 23% respectively.

[Ref. 4:p. 7]

TABLE II  
TURBOFAN PERFORMANCE COMPARISON

$M_0 = 0.79$ ,  $h=35000$  ft.

ENGINE [Ref. 4:P.7]:

$F/m = 30.185$  lbf/(lbm/sec)

$SFC = 0.832$  (lbm fuel/hr)/lbf thrust

	ENGINE	ONX
		$Cp_c = 0.2434$
		$Cp_t = 0.2508$
$F/m$	30.18	33.937
SFC	0.832	1.0926
% Difference $F/m$	0	10.8
% Difference SFC	0	23.8

The bypass ratio was varied keeping other parameters fixed. Using ENGINE, a very narrow range of bypass ratio was found for which the static pressures of the bypass stream and the core flow could be equal at the constant pressure splitter plate aft of the low pressure turbine. The results in Figure 6 show that common trends were obtained with ENGINE and ONX. As bypass ratio was increased, both SFC and specific thrust decreased. However, the effect on specific thrust was the largest. In fact, only a 5% decrease in SFC could be obtained at the cost of a 20-30% decrease in specific thrust.

Figure 6. Engine Performance Trends for ONX and ENGINE Varying Bypass Ratio

( $M_0 = 0.79$ ,  $h = 35000$  ft,  $\pi_t = 2.3$ ,  $\pi_c = 10.87$ , TIT =  $1860^{\circ}\text{R}$ )

To complete the comparison of ENGINE and ONX and to examine the predictions of the ENGINE program, the following parameters were varied and the results obtained for specific thrust and SFC were plotted in the indicated figures: 1) exit Mach number from the LPT (Figure 7); 2) maximum temperature in the combustor (Figure 8); 3) fan pressure ratio (Figure 9); and 4) compressor pressure ratio (Figure 10).

Figure 7. Effect of LPT Exit Mach Number (AMACH8) on Specific Thrust and SFC

( $M_0 = 0.79$ ,  $h = 35,000$  ft,  $\pi_f = 2.3$ ,  $\pi_c = 10.87$ , TIT =  $1860^\circ R$ )

As shown in Figure 7, the LPT exit Mach number had little effect on the specific thrust or on the SFC.

In Figure 8, results are shown for varying turbine inlet temperature obtained using ENGINE with bypass ratio allowed to vary and with ONX with bypass ratio fixed. In the cases shown in Figure 8, the bypass ratio of ENGINE was allowed to vary such that the static pressure at the splitter plate, where the bypass air is mixed with core air, was matched. The mixed exhaust forced higher values of bypass ratio as the TIT was increased. The higher bypass ratio allowed the specific thrust to remain fairly constant. Since significantly more air was bypassed, less fuel was required to produce the same specific thrust as the TIT was increased. Since the bypass ratio increased, the SFC decreased as the TIT increased.

The results from ONX plotted on Figure 8 show the effect of increasing TIT while keeping bypass ratio constant. Fixing the bypass ratio resulted in increased specific thrust but at the price of increased SFC.

Figure 8. Effect of Varying TIT on Specific Thrust and SFC  
 $(M_0 = 0.79, h = 35,000 \text{ ft}, \pi_f = 2.3, \pi_c = 10.87, \text{TIT} = 1860^\circ\text{R})$

The range of fan pressure ratio was taken to be between 1.0 and 4.0. Figure 9 shows the performance calculated as the fan pressure ratio was varied between 1.0 and 3.4. ENGINE required that the bypass ratio vary to satisfy the equal-static-pressure condition at the splitter plate. A very narrow band of fan pressure ratios was obtained if the bypass ratio was also specified. ONX produced a broader range of values for a specified bypass ratio.

Figure 9. Effect of Varying PRLC on Specific Thrust and SFC  
 $(M_0 = 0.79, h = 35,000 \text{ ft}, \pi_c = 10.87, \text{TIT} = 1860^\circ\text{R})$

The result of varying compressor pressure ratio is shown in Figure 10. The bypass ratio was fixed at  $\beta = 0.5$ . ENGINE predicted a minimum SFC for compressor pressure ratio range between 11.5 and 12.5 (whereas the minimum predicted by ONX was greater than 20). It is clear from the curves in Figure 10 that a pressure ratio less than that for optimum SFC would be chosen to obtain a significant improvement in specific thrust.

Figure 10. Effect of Varying PRHC on Specific Thrust and SFC  
 $(M_o = 0.79, h = 35,000 \text{ ft}, \pi_c = 2.3, \text{TIT} = 1860^\circ\text{R})$

#### IV. WAVE ROTOR ANALYSIS

##### A. SUMMARY DESCRIPTION

The wave rotor component and the combustion chamber can be considered to be combined to form a two port component called a gas generator. Other models of the wave rotor component are possible, but the gas generator model is the most straightforward. The equations and code for the wave rotor flow modeling used in the WRCOMP program are described in Reference 9. The equations for the wave rotor component as a gas generator included in the ENGINE code are derived in Reference 4. Figure 11 shows an unwrapped wave rotor and a simplified wave diagram [Ref. 1:p. 38]. Reference 1 describes the gas generator process as a filling, emptying, filling and emptying process.

The process can equally be described as two scavenging processes separated by periods of stationary flow within the rotor. There is a low pressure scavenge at station (4) and a high pressure scavenge at station (2). The combustion exhaust gas initially compresses the air inside the wave rotor and then is scavenged to (4) by the incoming air at the low pressure port (1). When the high pressure exhaust port opens, the high pressure gas inside the wave rotor exits to the HPT and effectively scavenges the wave rotor [Ref. 15:p. 63].

Figure 11. Unwrapped Wave Rotor Component [Ref. 1:p. 38]

In the ENGINE program, the gas generator is modelled as an internal combustion process in which a gain in total pressure and a rise in the total temperature is achieved. The performance of the gas generator is expressed as a function of the static pressure ratio, the total pressure ratio and the total temperature ratio across the inlet ports [Ref. 3:p. 14].

#### B. INTERFACE WITH ENGINE PERFORMANCE CODE

WRCOMP can be run alone or in conjunction with the ENGINE code. Since the VAX system operates in windows, both programs can be run simultaneously. Both procedures for running WRCOMP are outlined in Appendix B. The original code used data statements in SI units. It was modified to accept input pressures in psi, temperatures in °R, density in lbm per ft<sup>3</sup>,

gamma, fuel air ratio (f), and wave rotor exit Mach number. In the coding, the analysis is nondimensionalized to the input parameters. An output file, WRPERF1.OUT, was incorporated to store the input parameters and to convert the English units to SI units. Routines were added to compute the procedures outlined in Reference 4 and to send the output to WRPERF1.OUT. The DISSPLA plotting routines were disabled. In practice, WRCOMP is run until the mass flow into the wave rotor is equal to the mass flow out. Adjustments are made progressively to RREF, the reference density inside the wave rotor, until the mass flows are equal. For 1681 iterations, a CFL number = 0.6, a grid cell width of 0.01, and performing 20 Riemann iterations, the total run time was about 14 minutes on the VAX. An example output is presented in Appendix B.

From experience with WRCOMP and ENGINE, it is easier to keep the overall pressure ratio constant for a series of test cases. By keeping the overall pressure ratio constant, the outlet pressure from the HPC stays the same. If the outlet pressure from the HPC is the same and the performance parameters for the wave rotor are kept the same, then the value for the reference density which satisfies the mass flow solution for WRCOMP also stays the same.

In practice, it is better to vary the overall pressure ratio and maintain the same turbine inlet temperature. This allows optimizing the fan, the compressor and the wave rotor based on realistic cycle constraints.

## V. LOW BYPASS TURBOFAN CYCLE CALCULATIONS

### A. GENERAL CONSIDERATIONS

The present work has been concentrated on the low bypass turbofan engine, and what performance improvements can be obtained by incorporating a wave rotor component. The initial calculations have been made without reference to a specific vehicle and mission. Considerations which underlie the calculations and which limit their scope are discussed in the following paragraphs.

The characteristics of low bypass turbofans provide a reasonable match to the performance requirements for cruise missiles and RPV's. However, the design limitations for the components of a cruise missile may vary significantly from those of an RPV, even though the two engines may have very similar thrust requirements. A cruise missile may require compact packaging and "low cost design" as it is considered a "throw-away" or one-time-use engine, thereby relaxing the TIT and cooling requirements. An RPV may require a lower TIT to prolong its service life.

Some limitations are inherent in the bypass engine type. A turbofan with mixed exhausts may be bypass ratio limited. The bypass air is mixed with the core air at the splitter plate, where the static pressures must match. If the Mach number of the bypass air is too low, the losses are too great.

Reasons for mixing the exhaust streams are to reduce engine noise and to reduce the IR signature by reducing the temperature of the core air by mixing with the cold bypass air. There is an improvement in performance ideally if mixing occurs internally when there is a large temperature difference between the two streams. [Ref. 8:pp. 165, 172]

The present representation of the wave rotor component is somewhat limited. The modeling associated with instantaneous port opening and closing may require further investigation. Slow port openings may provide more efficient wave rotor operation at length to width ratios below three and stagnation pressure losses are predicted to increase as the length to width ratio increases from three to six [Ref. 1:p. 236].

In performing cycle calculations, care must be taken to use realistic inputs for the wave rotor pressure ratio. Reference 1, p. 18, suggests some practical limits. As the static pressure ratio (SPR) increases, the efficiency of the wave rotor decreases. For good efficiency, total pressure ratios should be about 2.0. In the gas generator model, or pressure gain combustor, the total pressure ratio (TPR) should range from 1.1 to 2.0, corresponding to a total temperature (TTR) range between 1.5 to 3.8 [Refs 14; 15:p. 707].

The treatment of the wave rotor as an ideal component in the engine cycle is a limitation which eventually must be removed. The engine SFC and specific thrust depend greatly on the component efficiencies used in the performance

calculations. Their affects are not always obvious. A key parameter in turbofan engine design is the bypass ratio. As the bypass ratio increases, specific thrust decreases but SFC decreases to a minimum and then increases [Ref. 8:p. 163]. The optimum arrangement becomes dependent on the efficiencies attained by the individual components.

#### B. RESULTS

A study was conducted using WRCOMP and ENGINE to compare a turbofan with mixed exhausts and incorporating a wave rotor, with the baseline engine operating with the same turbine inlet temperatures. Table III lists the input parameters used in the comparison. A list of the component efficiencies is given in Appendix A.

In maintaining a constant TIT, the effect of adding a wave rotor component to the turbofan was to change both the SFC and the specific thrust. The results obtained for an engine designed with a wave rotor component operating in a gas generator mode are shown in Figure 12.

For each run the fan pressure ratio ( $\pi_f$ ) was fixed and the compressor pressure ratio ( $\pi_c$ ) was varied. Initially, the bypass ratio was allowed to vary to satisfy the equal-static-pressure requirement at the splitter plate, for a mixed exhaust. The calculated bypass ratio for all the test cases ranged broadly from zero to three. The overall pressure ratio was varied by fixing the fan and the wave rotor pressure

TABLE III  
RANGES OF INPUT PARAMETERS IN ENGINE COMPARISON

---

$M_o$ $h$ TIT $M_{LPT}$	BASELINE TURBOFAN	TURBOFAN WITH WAVE ROTOR
$\beta$ (bypass ratio)	0.5	varied
$\pi_f$	2.3	2.3 - 3.8
$\pi_c$	10.87	3.4 - 10.87
$\pi_{OPR}$	25.0	15 - 32
$\pi_{wr}$	--	1.6
Static Press. Ratio	--	0.4

---

ratios and varying the compressor pressure ratio. The fan pressure ratio was then increased. At each fan pressure ratio, a specific range of values was obtained for the compressor pressure ratio for which valid solutions existed. As the fan pressure ratio was increased, the feasible range of values for the compressor pressure ratio decreased (the best performance range for the overall pressure ratio was from 22 to 26), and the bypass ratio decreased. For example, for approximately the same TIT = 1860 and  $\pi_{OPR} = 23.6$  and for  $\pi_f = 2.3$  then  $\pi_c = 6.4$  and  $\beta = 1.802$ ; for  $\pi_f = 2.8$  then  $\pi_c = 5.3$  and  $\beta = 1.144$ . With the wave rotor incorporated, the SFC was consistently lower than the baseline turbofan. The specific

Figure 12. Effect of Varying PRHC and PRLC for a Turbofan with a Wave Rotor

( $M_0 = 0.79$ ,  $h = 35,000$  ft, AMACH8 = 0.4,  $\beta$  varies)

thrust was also higher than the baseline engine except for the case of  $n_f = 2.3$ .

Since a large bypass ratio may not be acceptable for a cruise missile (a larger bypass ratio would require a larger fan size which may not meet the packaging requirements), the

bypass ratio was set to  $\beta = 0.5$ , and the runs repeated. The results are given in Figure 13. A much smaller range of feasible compressor ratios resulted.

Figure 13. Effect of Varying Compressor Pressure Ratio at  $\beta = 0.5$  for a Turbofan

$(M_0 = 0.79, h = 35,000 \text{ ft}, \text{AMACH}8 = 0.4, \beta \text{ varies})$

Table IV shows the trade-off between % change in SFC and specific thrust (referred to the baseline turbofan engine) as the fan pressure ratio was changed.

TABLE IV  
PERCENT DIFFERENCE FROM BASELINE ENGINE

---

FAN PRESSURE RATIO	% DIFFERENCE SFC	% DIFFERENCE F/m
2.3	-15.62	-16.83
2.8	-10.22	+ 9.01
3.0	- 8.05	+19.38
3.2	- 7.33	+23.79
3.4	- 5.65	+32.07
3.6	- 4.09	+39.76
3.8	- 3.12	+44.86

---

Since it was not obvious that the improved performance was due to the wave rotor, the baseline engine performance was calculated as the fan pressure ratio was varied from 2.0 to 3.5. The results are shown in Figure 14. It can be seen in Figure 14 that, as the fan pressure ratio was increased, the SFC increased very slightly and the specific thrust was also almost constant. Thus the improved performance in Table IV was a direct result of the wave rotor.

Figure 14. Effect of Varying the Fan Pressure Ratio for the Baseline Turbofan

Table summarizes the results of the comparison of the baseline turbofan with an engine that incorporates a wave rotor component. The baseline performance is shown compared to the wave rotor turbofan with the same turbine inlet temperature (TIT), the same bypass ratio ( $\beta$ ), or the best specific thrust (ST). Of interest to a missile application, a 9% increase in specific thrust and a 7.3% decrease in SFC was obtained by incorporating a wave rotor into the baseline

turbofan and increasing the fan pressure ratio to 2.8, while maintaining  $\beta = 0.5$ .

Table V also infers other options available in particular applications. For example, if the capture area was not a design limitation, a higher bypass ratio ( $\beta = 0.91$ ) and fan pressure ratio ( $\pi_f = 3.0$ ) could improve the specific thrust (ST) by 16.5% and decrease the SFC by 6.2% while operating at the same TIT = 1860. Similar improvements in specific thrust (ST) and SFC were obtained for lower values of TIT at the specified  $\pi_f$ , as shown in the "best ST" entry in Table V.

## VI. CONCLUSIONS AND RECOMMENDATIONS

In the present study, the computer codes ENGINE and WRCOMP were installed and successfully operated on a VAX computer system. Modifications were made to enhance the utility of the programs and the results reported by the codes' author, A. Mathur, were reproduced.

Comparisons between the predictions of ENGINE and ONX (by J. Mattingly) led to the conclusion that the use of constant specific heats in ONX leads to less accurate results than can be obtained with ENGINE, which includes real gas behavior throughout. Indeed, the predictions of ONX were found to be highly sensitive to the input values of specific heats.

In first attempts to use the codes to examine the potential benefits of incorporating a wave rotor component in a mixed-exhaust by-pass fan engine, it was found that benefits were available which could not be obtained by varying the conventional engine components. For example, while maintaining the same by-pass ratio, a 9% increase in specific thrust and 7.3% decrease in SFC were predicted if, in addition to incorporating the wave rotor, the fan pressure ratio was increased from 2.3 to 2.8. Increases in specific thrust of almost 47% could be obtained with no change in SFC by increasing the fan pressure ratio to 3.8.

These results show that engines incorporating wave rotors can have improved performance over conventional gas turbines which are limited to the same turbine inlet temperature levels. Further extensions of the ENGINE code

- (1) to include other engine types
- (2) to include friction and heat transfer in the wave rotor simulation

are recommended. Also, studies to examine the effects of varying static pressure ratio and stagnation pressure ratio across the wave rotor, and of increasing turbine inlet temperature, should be carried out.

Finally, an experimental program to validate the wave rotor flow predictions and performance levels used in cycle studies, is required.

APPENDIX A  
PROGRAM ENGINE

A. PROCEDURES

1. Log on to the VAX

2. At the DCL prompt type:

```
$gksetup.....initialize GRAFkit software
$uis .....sends plots to screen
$run ENGINE1A.....runs ENGINE program
.....select options from screen
```

3. To make changes in ENGINE1A.FOR:

```
$gksetup .....only required once
$uis .....
$edit ENGINE1A.FOR ....to enter edit mode
.....
*C .....to enter full page editing
.....
<CTRL/Z> .....exits edit mode
*exit .....saves changes, DCL prompt returns
$FORTRAN ENGINE1A .....compiles FORTRAN code
$link ENGINE1A,'GKL' ..links ENGINE1A and GRAFkit
$run ENGINE1A
.....follow screen instructions
```

4. To send your results to a laser printer:

```
$gksetup .....initialize GRAFkit
.....environment
$ln03 .....sends output to laser printer
$define gk_out plot.dat .sends output to <fn>.<ft>
.....where plot.dat is your output
.....file name
$ln03s_sp .....output to laser for square
.....plot
$run ENGINE1A .....follow screen instructions
.....
$pprint/passall/que=ln03 plot.dat
.....plot.dat is the same file above
```

Note: Since the results are sent to an output file,  
"plot.dat", they will not appear on the screen.

## B. POLYTROPIC EFFICIENCY SAMPLE CALCULATIONS

The following sample calculations use the ENGINE output sample results from Section C in Appendix A.

### Compressor efficiency:

In terms of cycle parameters,

$$\eta_c = \frac{\text{ideal work interaction}}{\text{actual work interaction}} \quad A(1)$$

for a given pressure ratio. In terms of cycle parameters,

$$\eta_c = \frac{\frac{\gamma_c - 1}{\pi_c^{\frac{\gamma_c - 1}{\gamma_c}} - 1}}{\tau_c - 1} \quad A(2)$$

### Compressor polytropic efficiency:

For a given differential pressure ratio,

$$e_c = \frac{\text{ideal work interaction}}{\text{actual work interaction}} \quad A(3)$$

The relationship with compressor efficiency is.,

$$\tau_c = \pi_c^{\frac{\gamma_c - 1}{\gamma_c \cdot e_c}} \quad A(4)$$

so that

$$\ln \tau_c = \frac{\gamma_c - 1}{\gamma_c \cdot e_c} \cdot \ln \pi_c \quad A(5)$$

or

$$e_c = \frac{\gamma_c - 1}{\gamma_c} \cdot \frac{\ln \pi_c}{\ln \tau_c} \quad A(6)$$

For the fan (LPC):

From ENGINE1.DAT:

$$\begin{aligned}\gamma_c &= 1.4004 \\ \pi_f &= \frac{11.7}{5.1} = 2.2941 \\ \tau_f &= \frac{582}{444} = 1.3108\end{aligned}$$

giving, with Eq. A(6),

$$e_c = 0.8772$$

For the high pressure compressor (HPC):

From ENGINE1.DAT:

$$\begin{aligned}\gamma_c &= 1.3870 \\ \pi_c &= \frac{127.0}{11.7} = 10.8547\end{aligned}$$

giving, with Eq. A(6),

$$e_c = 0.9132$$

#### Turbine efficiency:

For a given pressure ratio,

$$\eta_t = \frac{\text{actual work interaction}}{\text{ideal work interaction}} \quad \text{A(7)}$$

In terms of cycle parameters,

$$\eta_t = \frac{1 - \tau_t}{1 - \pi_t \frac{\gamma_t - 1}{e_t \cdot \gamma_t}} \quad A(8)$$

Turbine polytropic efficiency:

For a given differential pressure ratio,

$$e_t = \frac{\text{actual work interaction}}{\text{ideal work interaction}} \quad A(9)$$

The relationship to turbine efficiency is

$$\tau_t = \pi_t \frac{e_t \cdot (\gamma_t - 1)}{\gamma_t} \quad A(10)$$

so that

$$\ln \tau_t = e_t \cdot \frac{\gamma_t - 1}{\gamma_t} \cdot \ln \pi_t \quad A(11)$$

or

$$e_t = \frac{\gamma_t}{\gamma_t - 1} \cdot \frac{\ln \tau_t}{\ln \pi_t} \quad A(12)$$

For the high pressure turbine (HPT):

From ENGINE1.DAT:

$$\begin{aligned}\gamma_t &= 1.3436 \\ \pi_t &= \frac{22.8}{123.2} = 0.1851 \\ \tau_t &= \frac{1295}{1860} = 0.6962\end{aligned}$$

giving, with Eq. A(12),

$$e_t = 0.8392$$

For the low pressure turbine (LPT):

$$\begin{aligned}\gamma_t &= 1.3612 \\ \pi_t &= \frac{11.6}{22.8} = 0.5088 \\ \tau_t &= \frac{1104}{1295} = 0.8525\end{aligned}$$

giving, with Eq. A(12),

$$e_t = 0.8899$$

ENGINE was modified to calculate the polytropic efficiency for comparison with ONX.

APPENDIX B  
PROGRAM WRCOMP

A. PROCEDURES

1. WRCOMP

- a. Log on to the VAX
- b. At the DCL prompt type:

\$run WRCOMP1A.....runs WRCOMP program  
.....select options from screen

2. INTERFACING WITH ENGINE

- a. Run ENGINE program in either configuration.
- b. \$type ENGINE1.DAT or  
\$print ENGINE1.DAT/que=la210\_1
- c. From the ENGINE1.DAT determine:
  - 1) Pressure out of HPC
  - 2) Temperature out of the HPC
  - 3) Gamma at the HPC
  - 4) Fuel-air ratio (f) from the burner
- d. Run WRCOMP1A using these values as inputs and make a guess for RREF.
- e. If min doesn't equal mout from WRCOMP, then change the guess for RREF and iterate until they are equal.
- f. Run ENGINE1A in the wave rotor configuration with the correct value for RREF.

## B. SAMPLE RESULTS

FILE WRPERF1.OUT FROM WRCOMP1A.FOR PROGRAM:

```
# OF TIME STEPS K= 2000
CFLNUM= 0.6000000
# OF RIEMANN ITER. (QSTOP)= 20
GRID CELL WIDTH DX= 0.01
PTO = 79.20000 psi
PTOTIN= 546064.8 Pa
RTIN = 0.1956737 lbm/ft^3
RTOTIN = 3.134375 kg/m^3
PSEXIT1 = 75.54148 psi
PSEXIT = 520840.2 Pa
PREP1 = 188.8537 (psi)
PREP = 1302101. (Pa)
xref = 0.1800000 m
xref1 = 0.5905512 ft
```

### TIMING AND MASS FLOW BALANCE:

INLET PORT OPENS AT:		
N= 741	TTOTAL= 1.2576689	TIME= 0.0003768
EXHAUST PORT CLOSES AT:

## APPENDIX C

### COMPUTER SYSTEM AIDS

#### A. TRANSFERRING FILES

##### 1. FROM MAINFRAME TO AERO PC LAB

The following procedures use SIMPC to download programs from the NPS mainframe to the Aero Department's PC Lab. The modem and SIMPC hooked up to the IBM PC-XT-2 in the Aero PC lab. The following **boldfaced** commands outline the procedures.

```
C\ <dir> >cd\SIMPC.....change dir to SIMPC dir  
C\SIMPC>SIMPC ACCESS.SIM...execute SIMPC macro ACCESS.SIM  
...  
...  
LOGON: 9812P ....logon to mainframe (user number)  
PASSWORD: _____ ....enter your mainframe password  
...  
...  
...  
<enter> ....executes your PROFILE.EXEC  
...  
...  
FORSIMPC GET ENGINE FORTRAN A1..file to copy from  
mainframe  
...  
...  
A:ENGINE.FOR  
...  
...  
FORSIMPC PRINT ENGINE FORTRAN A1..optional if you wanted  
to send your file to the current printer.  
LOGOFF ...logoff the mainframe  
<ALT> <G> ...hangs up the modem  
<ALT> <Q> ...quits SIMPC and returns to DOS
```

The procedure above uses the macro ACCESS.SIM which was written specifically to link between the Aero PC lab and the NPS mainframe.

## 2. FROM AERO P.C. LAB TO VAX SYSTEM

The following procedure uses PROCOMM, an executable modem link, and ALT 0, a modem macro written specifically to link the Aero PC lab to the Aero VAX lab. KERMIT is the actual file transferring program.

```
C\ <dir> >cd\COM...change to COM directory.  
PROCOMM .executable program  
<ALT> 0 .macro modem link  
ATDT2953  
CONNECT  
USERNAME: GUEST    .choose username  
PASSWORD: _____ .password will not appear  
  
Are you logged on from a PC? Y  
Do you want to connect to WASP? Y  
  
Username: _____ .typical VAX logon  
Password: _____ .  
  
C\>KERMIT ..executes file transfer program  
  
to send a file:  
Receive FRCOMP1.FOR...Program you wish to call  
F3: WRC P.FOR ... file you wish to send but this file  
must be in the PROCOMM dir on the C (hard) drive!  
  
LOGOFF      ...logoff the VAX  
<ALT> X ...exits PROCOMM
```

If you have any difficulties F10 is the help menu!

## B. USING "SIGHT" UTILITY ON THE VAX

SIGHT is a utility drawing program available on the Aero Department VAX computer. It was used to create pop-up menus for the configurations for the ENGINE program. To run SIGHT, at the DCL prompt enter

```
$SIGHT
```

A pop-up menu provides simple instructions. Save your drawing as a <fn>.UIS file and then use the VAX "render" command to create your output file as a <fn>.REN file. An example for sending creating and sending an output file to the laser (ln03) printer is:

```
$RENDER <fn>.UIS/DEVICE_TYPE=ln03  
$PRINT/PASSALL/QUE=ln03 fn.REN
```

SIGHT can be used to generate a picture from inside a program. This can be done by inserting the following statement in a (FORTRAN) program.

```
CALL LIB$SPAWN ('RENDER <fn>.UIS')
```

This was done for the ENGINE program.

### C. GRAFkit PROCEDURES

PLOT3.FOR is a GRAFkit plotting program which was incorporated in the ENGINE1A.FOR program. PLOT3.FOR will be available as an engine performance plotting program on the VAX network. It can accept up to 50 separate data inputs for a selected X-axis, a Y1-axis for specific thrust, and a Y2-axis for specific fuel consumption. The instructions for running PLOT3.FOR are included in the comments section of the program listing.

#### PLOT3.FOR program listing

```
C----THIS PLOTTING PROGRAM USES GRAFKIT SOFTWARE-----
C----ENSURE THE FOLLOWING SEQUENCE IS ENTERED PRIOR TO
C    EXECUTION OF PLOT3:
C        logon the VAX
C        $GRKSETUP
